Description of ER Diagram

In the given ER Diagram, we have 8 entities, namely:

- User

The User has attributes which describe his unique identification number, contact details, login details, health details and recent travel history

- Patient

The Patient is a user who has his own unique patient ID, current status, disease, covid variant if covid infected and date of death if deceased

- Location

This entity has the Pin Code, City, District and State

- Hospital

A Hospital has its ID, name and the data of various resources such as ICU, Oxygen Cylinders, Beds and Ventilators

- Vaccination Centre

A Vaccination Centre has its ID, name and vaccine data

- Testing Lab

A Testing Lab has its ID, name and testing kit data

- Symptoms

The entity Symptoms has various symptom names listed along with their unique ID

- Social Media

The Social Media entity has news which is scraped from social media. Every news has its own unique ID along with whether it's a rumor or not and the action taken to stop the further spread of rumor.

The relationships in the ER Diagram are:

- **patient_status** : This relation defines whether a user is a patient or not, ie, whether he is suffering from a disease or not.
- **experiencing** : This relation defines the symptoms experienced by a specific user.
- **consult_hospital** : This relationship defines the hospital which a particular patient is consulting and whether he is admitted or not along with the treatment he received. If admitted, the relation also has an **Admit_Date** attribute. This is a many to many relationship.
- **situated_at** : This relation is defined between Hospital and Location, Vaccination Centre and Location and Testing Lab and Location. This is a one to many relationship and has an attribute to store the locality of the corresponding entity. Also, it is mandatory that every record in the Hospital, Vaccination Centre and Testing Lab has to be related to a record in Location.
- **test_status** : This relationship is defined between a User and a Testing Lab and contains the attributes to store test date, test result and result date. This is a many to many relationship.
- **residence_at** : This relationship is defined between User and Location and stores the address of the user. This is a one to many relationship.
- **vaccine_status** : This relationship is defined between user and Vaccination Centre and stores the data for number of doses given and the date at which each dose is administered. This is a many to many relationship.
- **news_location** : This is a relationship defined between Social Media and Location and this defines that the news is pertaining to which location. This is a many to many relationship.

Features

By using this database structure the users, government agencies and healthcare officials can access and interpret the data in various ways. This database can provide the progress of the pandemic with time as we have stored dates of all the new found cases and the number of deaths can also be calculated using our model. Also the inventory can also be taken care of as we have stored data of various things used in hospitals, vaccination centers and testing labs. As we have also used the Location entity, we can also classify or filter our required data according to given location and use it to monitor the progress of the pandemic. Contact tracing can also be done as we store recent travel history and his residential address in the database model.

Our model has additional functionality to also see which symptoms are more common among the general public and the percentage of tests which have a positive result. We can also find the number of fully, partially and non vaccinated people.

Thank You
